

Programming with Android: Notifications, Threads, Services

Luca Bedogni

Marco Di Felice

Dipartimento di Scienze dell'Informazione

Università di Bologna

Outline

Notification Services: **Status Bar** Notifications

Notification Services: **Toast** Notifications

Thread Management in Android

Thread: **Handler** and **Looper**

Services: Local Services

Services: Remote Services

Broadcast Receivers

Android: **Where are we now ...**

TILL NOW → Android Application structured has a single **Activity** or as a group of Activities ...

- **Intents** to call other activities
- **Layout** and **Views** to setup the GUI
- **Events** to manage the interactions with the user

Activities executed only in **foreground** ...

- What about *background* activities?
- What about *multi-threading* functionalities?
- What about *external events* handling?

Android: **Where are we now** ...

EXAMPLE: A simple application of *Instantaneous Messaging (IM)*

- Setup of the application **GUI** ✓
- GUI **event** management ✓
- Application **Menu** and **Preferences** ✓
- *Network functionalities* (send/receive messages) ✓
- Updates in **background** mode ✗
- **Notifications** in case of message reception in background mode ✗

Android: Service Notifications Types

Service Notifications: *Mechanism to notify information to the end-user on the occurrence of specific events*

Status Bar Notifications

Toast Notifications

Android: Status Bar Notifications

- Used by *background services* to notify the occurrence of an event that requires a **response** ... without *interrupting the operations of the foreground activities!*

- Display an **icon** on the Status Bar (top screen)

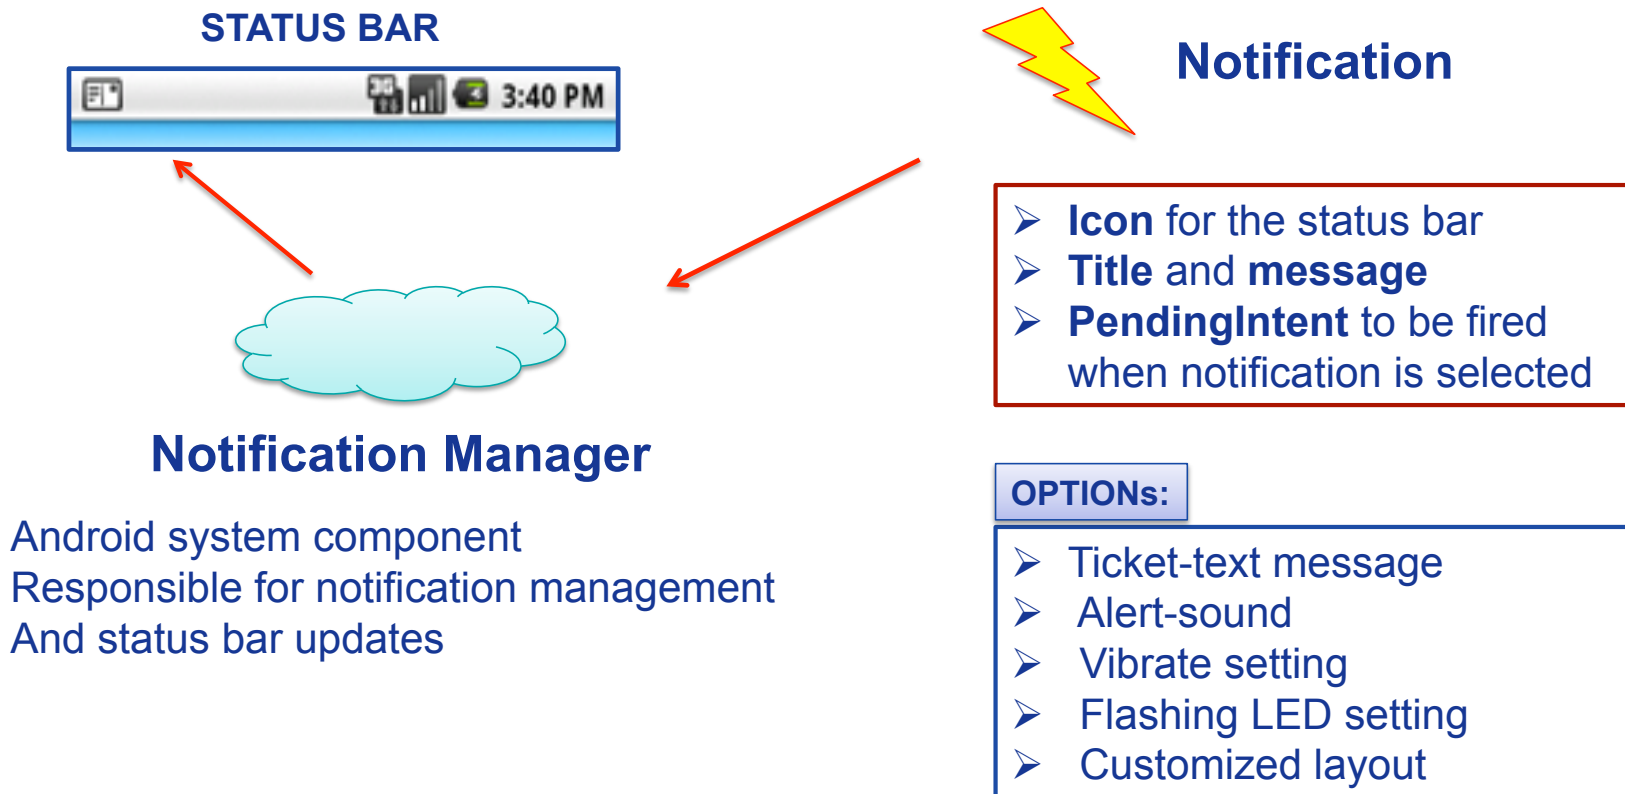

- Display a **message** in the Notification Window

- Fire an **event** in case the user selects the notification

Android: Status Bar Notifications

Android: Status Bar Notifications

➤ Follow these steps to send a Notification:

1. Get a reference to the Notification Manager

NotificationManager nm=(NotificationManager) **getSystemService**
(Context.NOTIFICATION_SERVICE)

2. Build the Notification message

```
public Notification(int icon, CharSequence tickerText, long when)  
public void setLatestEvent(Context context, CharSequence contentTitle,  
CharSequence contentText, PendingIntent intent)
```

3. Send the notification to the Notification Manager

```
public void notify(int id, Notification notification)
```

Android: Status Bar Notifications

Build the notification object

```
// Specify icon, ticket message and time  
Notification notification = new Notification(R.drawable.icon, "This is a very  
basic Notification to catch your attention!", System.currentTimeMillis());
```

Define what will happen in case the user selects the notification

```
// Build an explicit intent to NotificationActivity  
Intent intent = new Intent(this, NotificationActivity.class);  
PendingIntent pIntent = PendingIntent.getActivity(this, 0, intent,  
PendingIntent.FLAG_CANCEL_CURRENT);
```

Android: Status Bar Notifications

Add (optional) flags for notification handling

```
// Specify that notification will disappear when handled  
notification.flags |= Notification.FLAG_AUTO_CANCEL;
```

Send the notification to the Notification Manager

```
// Set short and long message to be displayed on the notification window  
// Set the PendingIntent  
notification.setLatestEventInfo(this, "Notification", "Click to launch  
NotificationActivity", pIntent);  
notificationManager.notify(SIMPLE_NOTIFICATION_ID, notification);
```

Android: Status Bar Notifications

Add a **sound** to the notification

```
// Use a default sound  
notification.defaults |= Notification.DEFAULT_SOUND;
```

Pass an **URI** to the sound field to set a different sound

```
notification.sound = Uri.parse(file:///sdcard/path/ringer.mp3);
```

Use **FLAG_INSISTENT** to play the sound till notification is handled

```
notification.flags |= Notification.FLAG_INSISTENT;
```

Android: Status Bar Notifications

Add **flashing lights** to the notification

```
// Use a default LED  
notification.defaults |= Notification.DEFAULT_LIGHTS;
```

Define *color and pattern* of the flashing lights

```
notification.ledARGB = 0xff00ff00;  
notification.ledOnMS = 300;  
notification.ledOffMS = 1000;  
notification.flags |= Notification.FLAG_SHOW_LIGHTS;
```

Android: Status Bar Notifications

Add **vibrations** to the notification

```
// Use a default vibration  
notification.defaults |= Notification.DEFAULT_VIBRATE;
```

Define *the vibration pattern*

```
// Set two vibrations, one starting at time 0 and with duration equal to 100ms  
long[] vibrate={0,100,200,300};  
notification.vibrate = vibrate;
```

Android: Status Bar Notifications

Some **flags** that can be used (see the documentation)

- **FLAG_NO_CLEAR**: Notification is not canceled
- **FLAG_ONGOING_EVENT**: Notify ongoing events (e.g. a call)
- **FLAG_AUTO_CANCEL**: Notification disappears as handled
- **FLAG_INSISTENT**: Reproduce sound till notification is handled
- **FLAG_FOREGROUND_SERVICE**: Notification from an active service

... Also **PendingIntents** can have flags

- **FLAG_CANCEL_CURRENT**: PendingIntents are overwritten
- **FLAG_UPDATE_CURRENT**: PendingIntents are updated (*extra field*)

Android: Toast Notifications

A **Toast Notification** is a message that pops up on the surface of the window, and automatically fades out.

- Typically created by the *foreground* activity.
- *Display* a message text and then fades out
- **Does not accept events!** (use *Status Bar Notifications* instead)

Android: **Toast Notifications**

A **Toast Notification** is a message that pops up on the surface of the window, and automatically fades out.

```
Context context=getApplicationContext();  
  
// Define text and duration of the notification  
CharSequence text="This is a Toast Notification!";  
int duration=Toast.LENGTH_SHORT;  
  
Toast toast=Toast.makeText(context, text, duration);  
  
// Send the notification to the screen  
toast.show();
```

Android: **Processes** and **Threads**

- By default, all components of the same application run in the same process and thread (called “**main** thread” or “**UI**” thread).
- In **Manifest.xml**, it is possible to specify the process in which a component (e.g. an activity) should run through the attribute **android:process**.
- Processes might be killed by the system to reclaim memory.
 - **Processes’ hierarchy** to decide the importance of a process.
 - Five *types*: Foreground, Visible, Service, Background, Empty.

Android: Thread Management

- Android natively supports a **multi-threading** environment.
- An Android application can be composed of multiple *concurrent* threads.
- How to create a thread in Android? ... Like in Java!
 - extending the **Thread** class **OR**
 - implementing the **Runnable** interface
 - **run()** method executed when **MyThread.start()** is launched.

Android: Thread Management

```
public class MyThread extends Thread {  
  
    public MyThread() {  
        super ("My Threads");  
    }  
  
    public void run() {  
        // do something  
    }  
}
```

```
myThread m=new MyThread();  
m.start();
```

Android: Thread Management

The **UI** or **main** thread is in charge of dispatching events to the user interface widgets, and of drawing the elements of the UI.

- Do not block the UI thread.
- Do not access the Android UI components from outside the UI thread.

QUESTIONS:

How to update the UI components from worker threads?

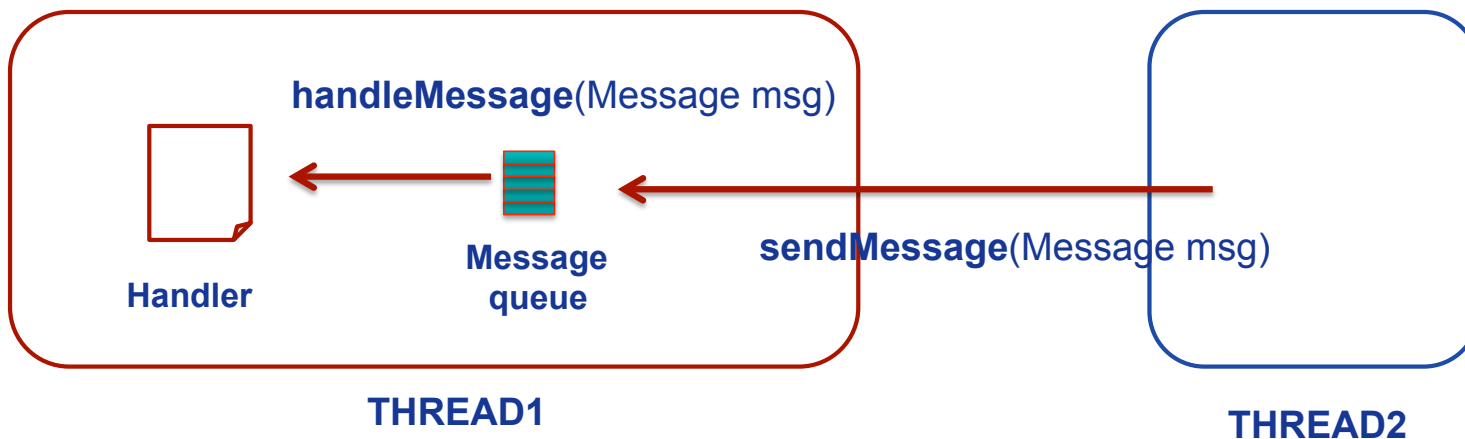

Android: Thread Management

Message-passing like mechanisms for Thread communication.

MessageQueue → Each thread is associated a queue of messages

Handler → Handler of the message associated to the thread

Message → Parcelable Object that can be sent/received

Android: Thread Management

Message loop is implicitly defined for the **UI** thread ... but it must be explicitly defined for worker threads.

HOW? Use **Looper** objects ...

```
public void run() {  
    Looper.prepare();  
    handler=new Handler() {  
        public void handleMessage(Message msg) {  
            // do something  
        }  
    }  
    Looper.loop();  
}
```

Android: **Services**

A **Service** is an application that can perform *long-running operations in background* and *does not provide a user interface*.

- **Activity** → UI, can be disposed when it loses visibility
- **Service** → No UI, disposed when it terminates or when it is terminated by other components

A Service provides a robust environment for background tasks ...

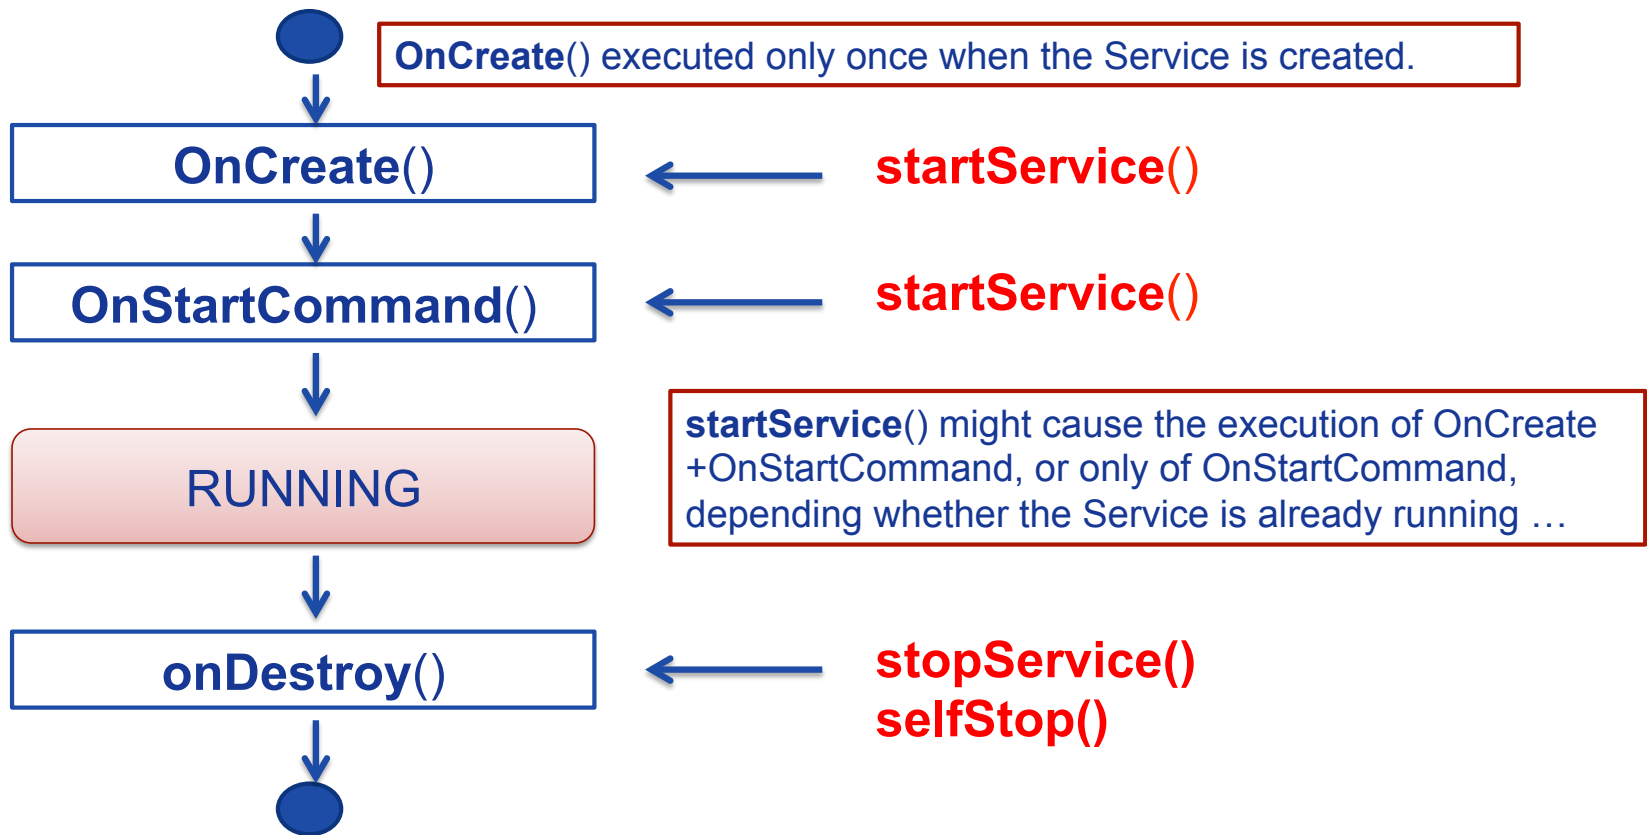

Android: **Services**

- A Service is started when an application component starts it by calling **startService(Intent)**.
- Once started, a Service runs in **background** indefinitely, even if the component that started it is destroyed.
- *Termination* of a Service:
 1. **selfStop()** → self-termination of the service
 2. **stopService(Intent)** → terminated by others
 3. System-decided termination (i.e. memory shortage)

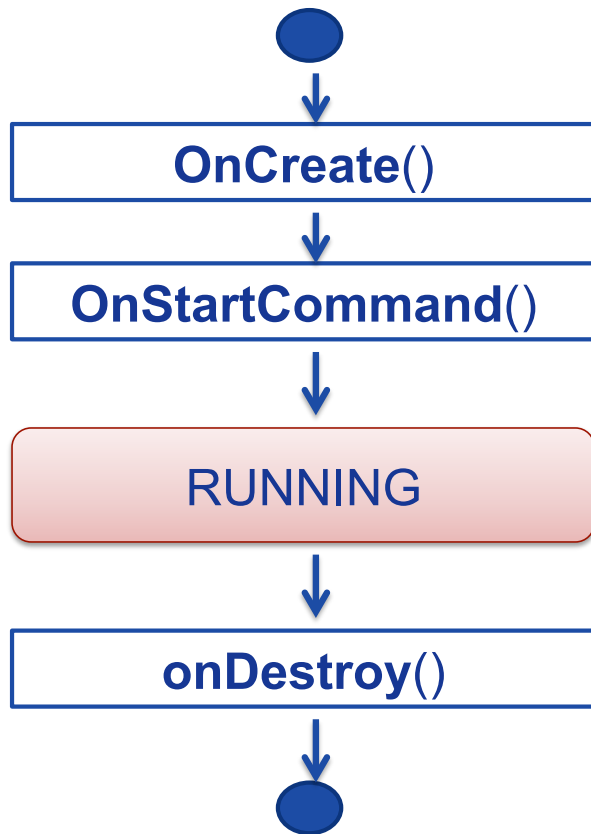

Android: Service Lifetime

Android: Service Lifetime

Two Types of Services:

1. **Local Services:** Start-stop lifecycle as the one shown.

2. **Remote/Bound Services:** Bound to application components. Allow interactions with them, send requests, get results, IPC facilities.

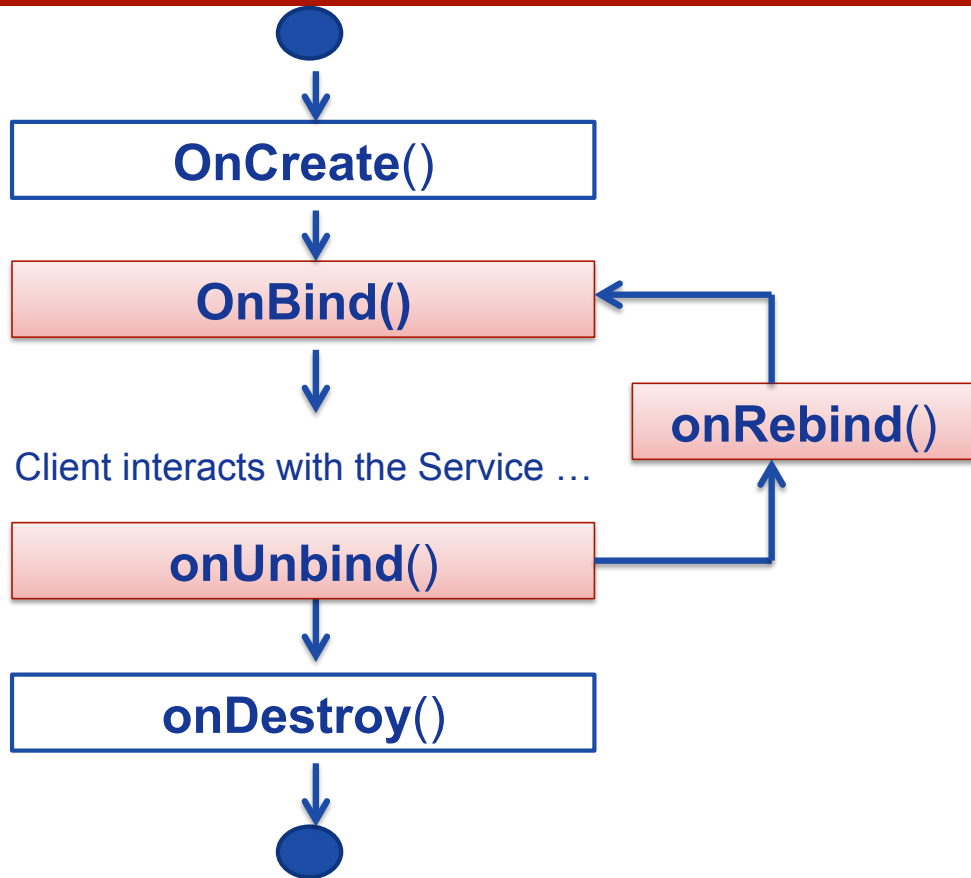

Android: **Foreground Services**

- A **Foreground Service** is a service that is continuously active in the Status Bar, and thus it is not a good candidate to be killed in case of low memory.
- The Notification appears between **ONGOING** pendings.
- To create a Foreground Service:
 1. Create a **Notification** object
 2. Call **startForeground(id, notification)** from **onStartCommand()**
- Call **stopForeground()** to stop the Service.

Android: Bound Service

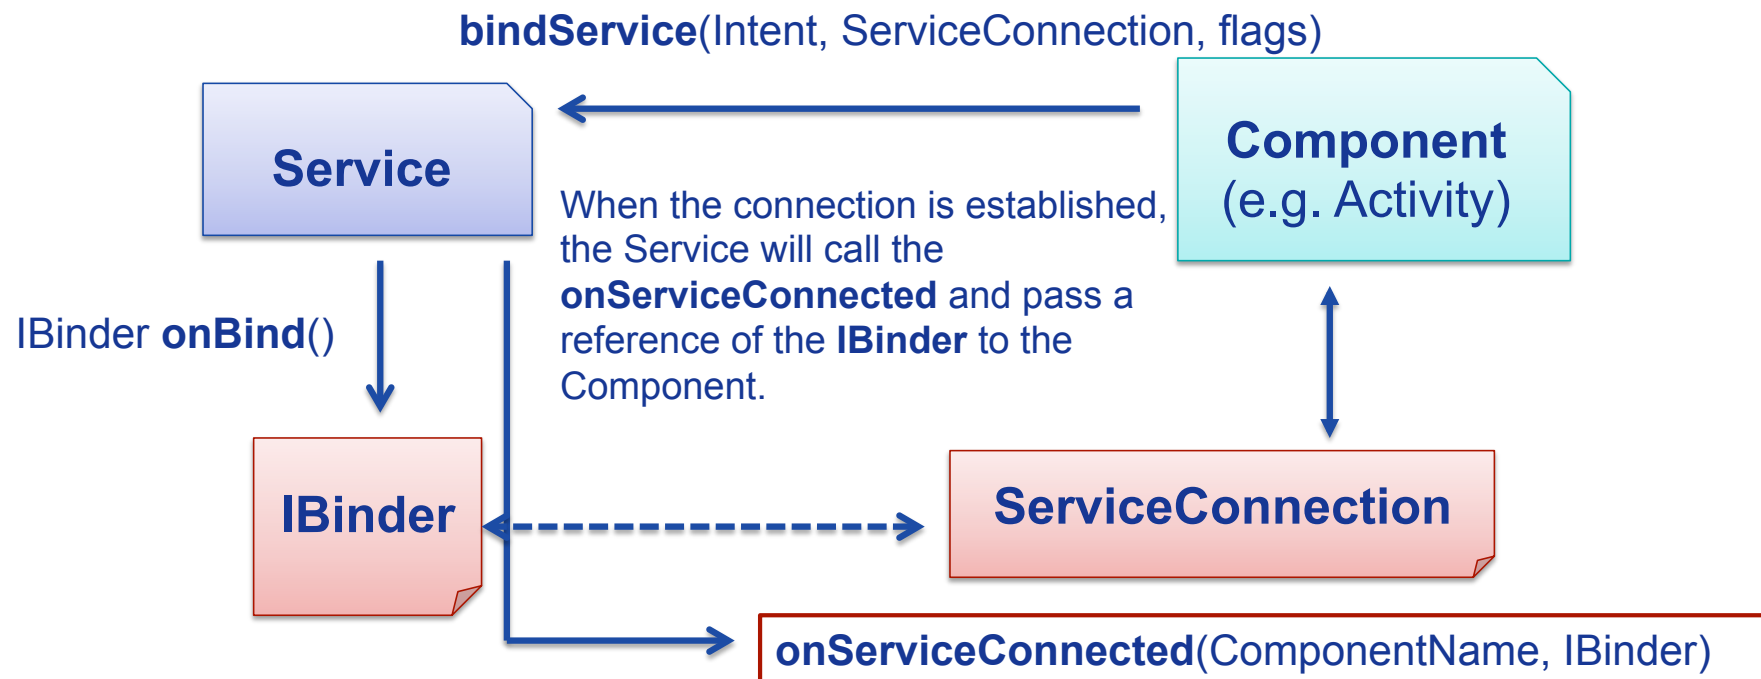

➤ A **Bound Service** allows components (e.g. Activity) to **bind** to the services, **send** requests, **receive** response.

➤ A **Bound Service** can serve components running on different processes (**IPC**).

Android: Bound Service

- Through the **IBinder**, the Component can send requests to the Service ...

Android: **Bound Service**

➤ When creating a Service, an **IBinder** must be created to provide an Interface that clients can use to interact with the Service ... HOW?

1. **Extending** the Binder class (local Services only)

- Extend the Binder class and return it from **onBind()**
- Only for a Service used by the same application

2. **Using** the Android Interface Definition Language (**AIDL**)

- Allow to access a Service from different applications.

Android: Bound Service

```
public class LocalService extends Service {  
    // Binder given to clients  
    private final IBinder sBinder=(IBinder) new SimpleBinder();  
  
    @Override  
    public IBinder onBind(Intent arg0) {  
        // TODO Auto-generated method stub  
        return sBinder;  
    }  
  
    class SimpleBinder extends Binder {  
        LocalService getService() {  
            return LocalService.this;  
        }  
    }  
}
```

Android: Bound Service

```
public class MyActivity extends Activity {
    LocalService IService;

    private ServiceConnection mConnection=new ServiceConnection() {

        @Override
        public void onServiceConnected(ComponentName arg0, IBinder bind) {
            SimpleBinder sBinder=(SimpleBinder) bind;
            IService=sBinder.getService();
            ....
        }

        @Override
        public void onServiceDisconnected(ComponentName arg0) {
        }

    };
};
```

Android: **Broadcast Receiver**

A **Broadcast Receiver** is a component that is activated only when specific events occur (i.e. SMS arrival, phone call, etc).

- **Registration** of the Broadcast Receiver to the event ...
 1. Event → **Intent**
 2. Registration through **XML** code
 3. Registration through **Java** code

- **Handling** of the event.

Android: Broadcast Receiver

A **Broadcast Receiver** is a component that is activated only when specific events occur (i.e. SMS arrival, phone call, etc).

BROADCAST RECEIVER LIFETIME

- Single-state component ...
- **onReceive()** is invoked when the registered event occurs
- After handling the event, the Broadcast Receiver is **destroyed**.

Android: Broadcast Receiver

- **Registration** of the Broadcast Receiver to the event ...
XML Code: → modify the **AndroidManifest.xml**

```
<application>  
  <receiver class="SMSReceiver">  
    <intent-filter>  
      <action android:value="android.provider.Telephony.SMS_RECEIVED" />  
    </intent-filter>  
  </receiver>  
</application>
```

Android: **Broadcast Receiver**

- **Registration** of the Broadcast Receiver to the event ...
In **Java** → **registerReceiver**(BroadcastReceiver, IntentFilter)

```
receiver=new BroadcastReceiver() { ... }
```

```
protected void onResume() {  
    registerReceiver(receiver, new IntentFilter(Intent.ACTION_TIME_TICK));  
}
```

```
protected void onPause() {  
    unregisterReceiver(receiver);  
}
```

Android: **Broadcast Receiver**

How to send the **Intents** handled by **Broadcast Receivers**?

- void **sendBroadcast**(Intent intent)
... No order of reception is specified
- void **sendOrderedBroadcast**(Intent intent, String permit)
... reception order given by the android:priority field

sendBroadcast() and startActivity() work on different contexts!
